

JMOA V2 - Evidence-Driven JVM Footprint Optimization

Build-time transformation, artifact proof, paired evidence validation, and memory attribution for Spring Boot.

-8,279 KB

median PSS | 3/3 wins | 6/6 valid

Why the result is credible

- Zero workload errors; V2-C CONFIRMED_WIN and V2-D attribution for every final row.
- PSS and Private_Dirty are primary; cgroup memory.current, NMT, smaps, heap, and histograms support attribution.
- Runtime artifact identity, materialization, class origins, and service-specific policy are part of the measured contract.
- Negative ASM, application-class, generated-family, and Patient AppCDS hypotheses remain rejected.

Claim boundary

Results are service-, artifact-, launch-mode-, and runtime-policy-specific. No universal CDS, startup, or memory claim.
